SUBJECT: Analysis of MSRE Zero-Power Flux Noise
Using Digital Techniques

TO: Distribution

FROM: T. W. Kerlin and S. J. Ball

COPY NO. 45

ABSTRACT

The record of the flux noise obtained during the zero-power operation of the MSRE with fuel circulating was analyzed by two different digital computer techniques. The indirect method consisted of calculating the autocorrelation function of the flux noise and subsequent Fourier analysis of this autocorrelation function to give the power spectral density. The direct method used a digital simulation of a band pass filter to concentrate the signal in the desired frequency range. The output of this filter was then squared and time-averaged to give the power spectral density.

Both methods were found to give comparable results at comparable costs. The results were also found to give reasonable agreement with previously published results obtained with analog methods. The value of β/l obtained by the digital method is 16.2 compared with 14.8 obtained in the earlier, analog study.

NOTICE

This document contains information of a preliminary nature and was prepared primarily for internal use at the Oak Ridge National Laboratory. It is subject to revision or correction and therefore does not represent a final report. The information is not to be abstracted, reprinted or otherwise given public dissemination without the approval of the ORNL patent branch, Legal and Information Control Department.

MSRE DATA	6
RESULTS	7
Indirect Method	7
Direct Method	18
CONCLUSIONS	18
Accuracy	20
Cost	20
Flexibility	20
Difficulty	21
Speed	21
APPENDIX	22

The first part of the document discusses the importance of maintaining accurate records of all transactions. It emphasizes that every entry should be supported by a valid receipt or invoice. This not only helps in tracking expenses but also ensures compliance with tax regulations. The second part of the document provides a detailed breakdown of the company's revenue for the quarter. It shows that sales have increased by 15% compared to the previous quarter, primarily due to the launch of a new product line. The third part of the document outlines the budget for the next quarter, highlighting areas where cost-cutting measures can be implemented without compromising the quality of the products. Finally, the document concludes with a summary of the overall financial performance and a forecast for the coming year.

The following table shows the monthly sales figures for the last quarter:

Month	Product A	Product B	Product C
Q1	1200	800	500
Q2	1500	1000	700
Q3	1800	1200	900

The data indicates a steady upward trend in sales across all product lines. This is a positive sign for the company's growth. However, it is important to monitor the profit margins closely, as the increase in sales volume may lead to higher operational costs. The management team should continue to focus on improving efficiency and reducing waste to maintain healthy profit margins.

In conclusion, the company has achieved significant milestones in the past quarter. The new product line has been well-received by the market, and sales have shown a strong upward trend. The management team is confident that the company is on a path to sustained growth and profitability in the coming year.

INTRODUCTION

Digital techniques were used to analyze the noise record obtained during the zero-power run of the MSRE. These data were previously analyzed by analog methods by Roux and Fry.¹ The purpose of the present analysis was to supplement the analog results and to further test the digital methods. One of the digital techniques used in this analysis had previously been used successfully in analysis of ORR noise data.²

METHODS OF ANALYSIS

Indirect Method

The steps in the indirect method are:

1. Calculate the autocorrelation function, $C_{11}(\tau)$, of the noise record using the following expression:

$$C_{11}(\tau) = \frac{1}{\tau_m} \int_0^{\tau_m} \varphi(t) \varphi(t + \tau) dt, \quad (1)$$

where

- τ_m = maximum correlation time, and
- φ = the neutron flux signal.

2. Fourier analyze the autocorrelation function. Since it is an even function with period $2\tau_m$, we obtain:

$$F_k \left\{ C_{11}(\tau) \right\} = \frac{2}{\tau_m} \int_0^{\tau_m} C_{11}(\tau) \cos \frac{k\pi}{\tau_m} d\tau. \quad (2)$$

3. Apply necessary corrections. These include:
 - a. Spectral windows to compensate for the fact that the Fourier analysis uses a finite integration time.
 - b. Filter corrections to remove the effect of a low-pass filter used to eliminate aliasing.
 - c. Background corrections.

Subject: Digital Calculation of the Power Spectral Density from Noise Data.

The corrected Fourier coefficient, $F_k \{C_{11}(\tau)\}$, at the frequency, $k\pi/\tau_m$ radians/sec, is the power spectral density (PSD) at that frequency.

Direct Method

In the direct method, the digitized noise signal is used as the input or forcing function to the differential equations representing a narrow band pass filter, and the resulting output of the filter is squared and integrated. The matrix exponential technique³ is used to solve for the transient response of the filter, which has the characteristics of a quadratic lag and a transfer function:

$$H(j\omega) = \frac{j\omega}{\omega_0^2 + 2\delta\omega_0 j\omega - \omega^2} \quad (3)$$

The center or resonant frequency of the filter is ω_0 , and the band width increases with increasing damping factor δ . The PSD may be computed from

$$\text{PSD} = \frac{\overline{q^2}}{\int_0^\infty |H(j\omega)|^2 d\omega} \left(\frac{\text{volts}^2}{\text{rad/sec}} \right), \quad (4)$$

(where $\overline{q^2}$ is the mean square filter output) if it is assumed that the PSD is constant within the band pass. For this filter

$$\int_0^\infty |H(j\omega)|^2 d\omega = \frac{\pi}{4\delta\omega_0} \text{ (radians/sec)}.$$

Provisions are also made in the code for correcting the PSD for any low-pass filter that may have been used to prevent aliasing, and for calculating the percent standard deviation of the PSD estimate.

MSRE DATA

The data previously used in the analog analysis¹ were digitized on the Millisadic digitizer. The data included records taken for the

³S. J. Ball and R. K. Adams, 'MATEXP, A General Purpose Digital Computer Program for Solving Nonlinear Ordinary Differential Equations by the Matrix Exponential Method,' USAEC ORNL Report in preparation.

reactor critical and for the background noise observed when the reactor was shutdown. The case considered was for the reactor primary salt circulating with no bubbles. The noise record for the critical reactor was passed through a low-pass filter consisting of a first order lag with a time constant of 0.0047 sec, then digitized with a sampling interval of 0.00284 sec. The background noise was also filtered and digitized in the same manner. Approximately 36,000 time points were used for both cases.

RESULTS

Indirect Method

Figures 1 through 3 show the autocorrelation functions obtained in the indirect analysis. All calculated points are plotted for the shorter correlation times, but only every tenth point was included after the curve had leveled out at longer correlation times. Figure 1 shows the autocorrelation function for signal plus background. Figure 2 shows the autocorrelation function for background only. The results shown in Fig. 3 were obtained by subtracting the background autocorrelation function from the autocorrelation function for signal plus background. This can be done if the signal and the background are uncorrelated. To show this, take a signal composed of uncorrelated time functions x and y , and calculate the autocorrelation function

$$\begin{aligned} C_{11}(\tau) &= \frac{1}{T} \int_0^T [x(t) + y(t)][x(t + \tau) + y(t + \tau)] dt \\ &= \frac{1}{T} \int_0^T x(t) x(t + \tau) dt + \frac{1}{T} \int_0^T y(t) y(t + \tau) dt \\ &\quad + \frac{1}{T} \int_0^T x(t) y(t + \tau) dt + \frac{1}{T} \int_0^T y(t) x(t + \tau) dt . \end{aligned} \quad (5)$$

Since x and y are uncorrelated, the last two integrals are zero and

$$C_{11}(\tau) = \frac{1}{T} \int_0^T x(t) x(t + \tau) dt + \frac{1}{T} \int_0^T y(t) y(t + \tau) dt . \quad (6)$$

Thus, if x is the signal and y is the background, we see that we get the autocorrelation function of the signal by subtracting the autocorrelation function of the background from the autocorrelation function of the composite signal. The improvement obtained from the background correction is quite apparent if one compares Fig. 1 with Fig. 3.
